**Question 1.** Given  $n$  intervals  $(s_i, f_i)$  where  $1 \leq i \leq n$ ,  $s_i$  and  $f_i$  is  $i$ -th interval's start and finish time, its duration time is  $f_i - s_i$ . Use any algorithm to get the maximize the total sum of mutually disjoint intervals.

1. we can use dynamic programming to solve this problem
2. for  $n$  intervals  $(s_i, f_i)$ , it's sorted so that  $f_1 \leq f_2 \leq \dots \leq f_n$
3. We use  $T(i)$  to represent the maximize total sum of intervals of  $((s_1, f_1), (s_2, f_2), \dots, (s_i, f_i))$ . each interval has two choices: added to the select set or not.

Define  $p(i)$ =the largest  $j < i$  that interval  $i$  doesn't overlap with  $j$ .

So the recurrence function is: 
$$T(i) = \max \begin{cases} T(p(i)) + f_i - s_i \\ T(i-1); otherwise \end{cases}$$

4. boundary condition  $T(0) = 0$
5. Implement the algorithm

---

**Algorithm 1** function maxSumInterval( $i$ )

---

Sort the interval according to  $f_i$ , so that  $f_1 \leq f_2 \leq \dots \leq f_n$ .

Start time array  $S=(0, s_1, s_2, \dots, s_n)$ , finish time array  $F=(0, f_1, f_2, \dots, f_n)$ .

- ```
1: global  $T[0, 1, 2, \dots, n]$ ,  $T[0]=0$ ;  $P[1, \dots, n]$ 
2:
3: for  $i \leftarrow 1$  to  $n$  do
4:   if  $T(p(i)) + f_i - s_i > T(i-1)$  then
      $T[i] = T(p(i)) + f_i - s_i$ 
      $P[i] = p(i)$ 
5:   else
      $T[i] = T[i-1]$ 
      $P[i] = -1$ 
6: Return  $T[n]$ 
```
-

6. we use  $P[1, 2, \dots, n]$  to print selected intervals

---

**Algorithm 2** function printInterval()

---

```
1: global  $P[1, \dots, n]$ 
2:  $i = n$ 
3: while  $P[i] \neq 0$  do
4:   if  $P[i] > 0$  then
     print  $i$ 
      $i = P[i]$ 
5: print  $i$ 
```

---

7. We use  $O(n \log(n))$  to sort. For each  $i$  we need  $O(n)$  to scan all the interval list and repeat  $n$  times, So the time complexity is  $O(n^2)$

8. source code: max\_selected\_intervals.cpp

**Question 2.** Let  $A = a_1 a_2 \dots a_m$  and  $B = b_1 b_2 \dots b_n$  be two strings of characters. we want to transform  $A$  into  $B$  using following operations:

delete a character

add a character

change a character

write a dynamic programming algorithm that finds the minimum number of operations needed to transform  $A$  into  $B$

1. Let  $F[i, j]$  denotes the minimum number of operations needed to transform  $a_1 a_2 \dots a_i$  to  $b_1 b_2 \dots b_j$ .

2. Recurrence relation

$$F[i, j] = \begin{cases} F[i-1, j-1]; & \text{if } a_i = b_j \\ \min \begin{cases} F[i-1, j-1] + 1; & \text{change} \\ F[i, j-1] + 1; & \text{add} \\ F[i-1, j] + 1; & \text{delete} \end{cases} & \text{otherwise} \end{cases}$$

3. Boundary conditions

$$F[0, k] = k \text{ for } k \text{ in } [0, n]$$

$$F[k, 0] = k \text{ for } k \text{ in } [0, m]$$

4. implement the non recursive algorithm, see algorithm ??

---

**Algorithm 3** function MinNumOper()

---

```
1: global  $F[1..m; 1..n]$ ,  $A[1..m]$ ,  $B[1..n]$ 
2: Initialize  $F[0, k] = k$  for  $k$  in  $[0, n]$  and  $F[k, 0] = k$  for  $k$  in  $[0, m]$ 
3: for  $i \leftarrow 1$  to  $m$  do
4:   for  $j \leftarrow 1$  to  $n$  do
5:     if  $A[i] == B[j]$  then  $F[i, j] = F[i-1, j-1]$ 
6:     else
7:        $F[i, j] = \min \begin{cases} F[i-1, j-1] + 1; \text{change} \\ F[i, j-1] + 1; \text{add} \\ F[i-1, j] + 1; \text{delete} \end{cases}$ 
8:   return  $F[m, n]$ 
```

---

5. in the main function, we can call the function *MinNumOper()* to find the minimum number of operations needed to transform A into B
6. time complexity of this algorithm is  $\Theta(mn)$
7. source code: min\_operation\_dp.cpp
